ON WASHINGTON GROUP OF CIRCULAR UNITS OF SOME COMPOSITA OF QUADRATIC FIELDS

MICHAL BULANT

Abstract. Circular units emerge in many occasions in algebraic number theory as they have tight connection (first discovered by E. Kummer) to the class group of the respective number field.

For example, E. Kummer has shown that in the case of cyclotomic field with prime conductor the index of the group of circular units in the full group of units is equal to the class number of the maximal real subfield of that field. His result was later generalized so we are now able to obtain information about class groups by the study of circular units.

In contrast to the case of cyclotomic field it is not clear how to define the group of circular units of a general abelian number field \( K \). In the literature there eventually turned up several possible definitions of a group of circular units.

One of these definitions (which appeared in the Washington’s book Introduction to cyclotomic fields – [7]) constructs the group of circular units to be as large as possible — it considers all circular units of the respective cyclotomic superfield which are lying already in the field \( K \).

This definition has some nice properties but also serious difficulties: generally we do not know neither explicit generators of the group nor the index of the group in the full group of units.

In this paper we present results about this index for some classes of abelian fields — namely for composita of quadratic fields satisfying an additional condition — obtained by the study of the relation between Washington group of circular units and the well-known Sinnott’s group of circular units. Methods of this paper use and slightly extend approach appeared in [4].

1. Introduction

For the understanding of the arithmetic of any algebraic number field \( K \) it is necessary to be able to work with its group of units \( E(K) \). Unfortunately it is not feasible to find a basis of the non-torsion part of \( E(K) \) (so called fundamental units) in the general case. We are therefore trying to approximate the group \( E(K) \) by an appropriate subgroup with a known set of independent generators. In the case of abelian extension of rational numbers this role is usually played by so-called circular units which are defined in the next section.

Throughout the whole paper we shall assume the field \( K \) to be an abelian field, i.e. a finite Galois extension of \( \mathbb{Q} \) with commutative Galois group. Often we will also work with cyclotomic fields; by the \( n^{th} \) cyclotomic field we understand the field \( \mathbb{Q}(\zeta_n) = \mathbb{Q}(e^{2\pi i/n}) \), where \( \zeta_n = e^{2\pi i/n} \) is a primitive \( n^{th} \) root of unity.

2. Circular units in abelian fields

Let us first consider the case of a cyclotomic field \( K = \mathbb{Q}(\zeta_n) \). Although we do not know explicit system of independent generators of \( E(\mathbb{Q}(\zeta_n)) \) we are able to construct a subgroup of \( E(\mathbb{Q}(\zeta_n)) \) of sufficiently low finite index — namely the group of circular units \( C(\mathbb{Q}(\zeta_n)) \) formed by the units of the form \( 1 - \zeta_n^a \):

\[
C(\mathbb{Q}(\zeta_n)) = \langle 1 - \zeta_n^a; a \in \mathbb{Z}, n \nmid a \rangle \cap E(\mathbb{Q}(\zeta_n)).
\]

A natural question arises — how to generalize this definition to the case of a general abelian number field? Unfortunately there is no unique way of definition of circular units in this case.
Trivially $C_S(K) \subseteq C_W(K)$.

Let us now discuss the construction of the basis for the group of circular units and the index in the full group of units. W. Sinnott has proved in [5] that

$$[E(Q^{(n)}): C(Q^{(n)})] = 2^e \cdot h_+^{Q(n)},$$

where $h_+^{Q(n)}$ is the class number of the maximal real subfield of $Q^{(n)}$ and $c$ is given by an explicit function of the number of primes ramified in $Q^{(n)}$. In [6], Sinnott has also stated the formula for the index $[E(K): C_S(K)]$ in the case of a general abelian field — in this case the formula unfortunately contains a non-explicit factor which has been calculated only in some special cases so far, e.g. when $K$ is a compositum of quadratic fields (see [3, Proposition 1] and Proposition 2). In the case of the alternative definition $C_W(K)$ we are not aware of any explicit formula for the index.

Construction of a basis of the group of circular units is generally more complicated than the calculation of the index described above. The easiest case is that of cyclotomic field of a prime power conductor, $K = Q^{(n)}$, where $n = p^l$, $p$ being a prime, $l$ any positive integer. In this case, a basis is the set

$$\left\{ \frac{1 - \zeta_n^a}{1 - \zeta_n}, 1 < a < \frac{n}{2}; (a,n) = 1 \right\}.$$

In the case of a general cyclotomic field the situation is much more complicated — similar bases were found independently by R. Gold and J. Kim (see [1]) and by R. Kučera ([2]). As we shall need this basis for our purpose later we present here the construction described in [2, Theorem 6.1]. In our description we limit ourselves to the case where the conductor of $K$ is a product of distinct primes.

**Proposition 1.** Let $n = p_1 \cdot p_2 \cdots p_l$ be the conductor of $K$ ($p_1 < p_2 < \cdots < p_l$ being primes).

Further let $X = \{ a \in \mathbb{Z}; 0 < a < n \}$ and $M$ be the set defined by

$$M = X \setminus \left( \left\{ a \in X; \exists i \in \{1, \ldots, l\} : p_i \nmid a \land \frac{a}{(a,n)} \equiv -1 \pmod{p_i} \right\} \right.$$\vspace{0.5cm}

\hspace{1cm} $\cup \left\{ a \in X; a \mid n \land 2 \nmid \# \{ i \in \{1, \ldots, l\}; p_i \mid a \} \right\}$\vspace{0.5cm}

\hspace{1cm} $\cup \bigcup_{k=1}^l \left\{ a \in X; p_k \nmid a \land \left( \frac{a}{(a,n) \cdot p_k} \right) > \frac{1}{2} \land \forall i \in \{k+1, \ldots, l\} : a \equiv (a,n) \pmod{p_i} \right\}\right\}.$

Then the set

$$\left\{ \frac{1 - \zeta_n^a}{1 - \zeta_n}; a \in M \land \forall i \in \{1, \ldots, l\} : \frac{n}{p_i} \nmid a \right\} \cup \left\{ \frac{1 - \zeta_n^{p_i}}{1 - \zeta_n} ; a \in M \land \frac{n}{p_i} \mid a, i = 1, \ldots, l \right\}$$

forms a system of independent generators of the non-torsion part of the group $C(Q^{(n)})$.

**Proof.** See [2, Theorem 6.1].

---

3. **Compositum of real quadratic fields**

Now let $K$ be a compositum of real quadratic fields, such that $K = \mathbb{Q}(\sqrt{p}; p \in J)$, where $J$ is a set of positive primes $p \equiv 1 \pmod{4}$ satisfying for any distinct $p, q \in J$ the relation $(p/q) = 1$ ($p$ is a quadratic residue modulo $q$ — and vice-versa).

For any $\emptyset \neq T \subseteq J$ we now define $\nu_T = \prod_{p \in T} p$, $K_T = \mathbb{Q}(\sqrt{p}; p \in T)$, and $\mathbb{Q}^T = \mathbb{Q}(\zeta_T)$, where $\zeta_T = e^{2\pi i/\nu_T}$. Further, for any $p \in J$ let $\sigma_p$ be a generator of $\text{Gal}(\mathbb{Q}^J/\mathbb{Q}^{(p)})$.

In the case of a compositum of quadratic field we are able to calculate the required index:

**Proposition 2.** Let $K = \mathbb{Q}(\sqrt{p}; p \in J)$, where $J$ is as above. Then

$$[E(K) : C_S(K)] = 2^{2^{2^J} - 1} \cdot h_K,$$

where $h_K$ is the class number of $K$.

*Proof.* See [3, Theorem 1], especially Remark following the proof of Theorem 1. Considering our restrictions put on the field $K$ we obtain the formula $[E(K) : C] = 2^{2^{2^J} - J - 1} \cdot h_K$ where the group $C$ considered in [3] is slightly enlarged group $C_S(K)$. From the discussions on pages 148–149 we finally obtain $[C : C_S(K)] = 2^{2^J}$. □

From the previous section we know that the group $C_S(K)$ of circular units of $K$ (in Sinnott’s sense) is generated by $-1$ and all conjugates of $\eta_T$, $\emptyset \neq T \subseteq J$, where

$$\eta_T = \begin{cases} \mathcal{N}_{\mathbb{Q}^T/K_T}(1 - \zeta_T)^{1 - \sigma_p} = \prod_{i=0}^{\nu_T - 2}(1 - \zeta_T)^{(-\sigma_p)} & \text{if } T = \{p\} \\ \mathcal{N}_{\mathbb{Q}^T/K_T}(1 - \zeta_T) & \text{if } \#T > 1 \end{cases}$$

For our calculations we shall need the following well-known norm relation:

**Lemma 3.** Let $m$ and $n$ be positive integers, $m \not\equiv 2 \pmod{4}$, $n \not\equiv 2 \pmod{4}$, and $m | n$. Then

$$\mathcal{N}_{\mathbb{Q}^n/\mathbb{Q}^m}(1 - \zeta_n) = (1 - \zeta_m)^{\prod_p(1 - \text{Frob}(p)^{(-1)})},$$

where $p$ is running through prime factors of $n$ not dividing $m$ and $\text{Frob}(p)$ is the Frobenius automorphism of $p$ on $\mathbb{Q}^m$.

*Corollary 4.* For any nonempty set $T \subseteq J$ and any prime $p \in T$

$$\eta_T^{1 + \sigma_p} = 1.$$

*Proof.* If $\#T > 1$ Lemma 3 gives

$$\eta_T^{1 + \sigma_p} = \mathcal{N}_{K_T/K_T\setminus\{p\}}(\mathcal{N}_{\mathbb{Q}^T/K_T}(1 - \zeta_T)) = \mathcal{N}_{\mathbb{Q}^T/K_T\setminus\{p\}}(1 - \zeta_T) =$$

$$= \mathcal{N}_{\mathbb{Q}^T/K_T\setminus\{p\}}(\mathcal{N}_{\mathbb{Q}^T/\mathbb{Q}^{(p)}}(1 - \zeta_T)) = \mathcal{N}_{\mathbb{Q}^T/\mathbb{Q}^{(p)}}(1 - \zeta_{T\setminus\{p\}})^{1 - \text{Frob}(p)^{-1}} = 1,$$

since the restriction of $\text{Frob}(p)$ to $K_{T\setminus\{p\}}$ is trivial as $(p/q) = 1$ for any $q \in T \setminus \{p\}$. The proof of the assertion in the situation when $\#T = 1$ is very similar. □

**Proposition 5.** If $K = \mathbb{Q}(\sqrt{p}; p \in J)$, where $J$ is a set of positive primes $p \equiv 1 \pmod{4}$ such that for any distinct $p, q \in J$ we have $(p/q) = 1$, then

$$C_S(K) = \langle -1, \eta_T; \emptyset \neq T \subseteq J \rangle.$$

*Proof.* We have to show that by omitting conjugates of $\eta_T$ we do not lose anything. But for any $p \in T$ we have $\eta_T^{\sigma_p} = \eta_T^{-1}$ by the previous corollary. □

**Lemma 6.** For any nonempty set $T \subseteq J$ the unit $\eta_T$ is a square in the appropriate field $K_T$.

*Proof.* For $T = \{p\}$ we have

$$\eta_{\{p\}} = \prod_{i=0}^{p - 2}(1 - \zeta_p)^{(-\sigma_p)} = \prod_{i=0}^{(p-3)/2} (-\zeta_p^{-1}(1 - \zeta_p)^2)^{(-\sigma_p)} = \varepsilon_p^{2},$$

where $\varepsilon_{\{p\}} = \prod_{i=0}^{(p-3)/2} (\zeta_p^{(p-1)/2}(1 - \zeta_p)^{(-\sigma_p)})$ is clearly an element of $\mathbb{Q}^m$. □
For \( T = \{ p_1, p_2, \ldots, p_t \} \subseteq J \) (where \( t \geq 2 \), \( p_1 = \min T \)) we have (index \( i \) in all subscripts running over the set \( \{1, \ldots, t\} \)).

\[
\eta_T = \prod_{1 \leq a \leq n_T} (1 - \zeta_T^a) = \prod_{1 \leq a \leq n_T} (1 - \zeta_T^a) (1 - \zeta_T^{-a}) = \prod_{1 \leq a \leq n_T} \left(-\zeta_T^{-a} \cdot (1 - \zeta_T^a)^2 \right) = \varepsilon_T^2
\]

where again

\[
\varepsilon_T = \prod_{1 \leq a \leq n_T} \zeta_T^{a-1} (1 - \zeta_T^a)
\]

is an element of \( \mathbb{Q}^T \) (by \( \langle x \rangle = x - [x] \) we denote the fractional part of a real number \( x \)).

It remains to show that for every nonempty \( T \subseteq J \) the unit \( \varepsilon_T \) is an element of \( K_T \). As \( \text{Gal}(\mathbb{Q}^T/K_T) = \langle \sigma_j^p; p \in T \rangle \) it is sufficient to prove that \( \varepsilon_T^{\sigma_j^p} = \varepsilon_T \) for any \( p \in T \). But from the above corollary we obtain \( (\varepsilon_T^2)^{p} = \eta_T^{1+\sigma_j} = 1 \), hence \( \varepsilon_T^{p} = \pm \varepsilon_T^{-1} \), and \( \varepsilon_T^{\sigma_j^p} = \varepsilon_T \).

As the unit \( \varepsilon_T \) is clearly also circular in \( \mathbb{Q}^T \), we obtain that \( \varepsilon_T \in C_W(K_T) \subseteq C_W(K) \) for any nonempty \( T \subseteq J \). Let us now form a subgroup \( D \) of \( C_W(K) \) generated by these \( \varepsilon_T \)’s:

\[
D = \langle -1, \varepsilon_T; \emptyset \neq T \subseteq J \rangle.
\]

Our present goal is to show that \( D \) is in fact equal to \( C_W(K) \) (i.e. we are going to prove the inclusion \( C_W(K) \subseteq D \)). As the conductor of \( K \) is \( n_J \) we have to consider a basis of the group \( C(\mathbb{Q}^{(n_J)}) \). Due to the special form of the conductor \( n_J \) (it is a product of distinct primes) we can describe this basis in a more compact form. In fact we shall describe only a subset of the basis in the following as it is fully sufficient for our purposes.

Let as usually \( T \) be any nonempty subset of \( J \). We have to distinguish two cases. If \( \#T > 1 \) let us define

\[
B_T = \left\{ 1 - \zeta_T^a; 1 \leq a \leq n_T, (a, n_T) = 1, \left\langle \frac{a}{\text{min } T} \right\rangle < \frac{1}{2}, \forall p \in T : a \not\equiv \pm 1 \pmod{p} \right\}
\]

and if \( T = \{ p \} \), let

\[
B_{\{ p \}} = \left\{ \frac{1 - \zeta_p^j}{1 - \zeta_p}; 2 \leq j \leq \frac{p-1}{2} \right\}
\]

From the description of the basis of \( C(\mathbb{Q}^{(n)}) \) in Proposition 1 it is easy to see that the union

\[
\bigcup_{\emptyset \neq T \subseteq J} B_T
\]

is a subset of the basis of \( C(\mathbb{Q}^{(n,J)}) \) and that the sets \( B_T \) are clearly pairwise disjoint. We are going to show (separately for the two mentioned cases) that for any nonempty \( T \) the element \( \varepsilon_T \) is an element of \( \mathbb{Q}^T \) generated by \( B_T \) (modulo torsion).

Keeping the notation \( T = \{ p_1, p_2, \ldots, p_t \} \subseteq J, t \geq 2, p_1 = \min T \), we have

\[
\eta_T^{\sigma p_1 \cdots \sigma p_t} = \prod_{1 \leq a \leq n_T} (1 - \zeta_T^a) = \prod_{1 \leq a \leq n_T} \left(-\zeta_T^{-a}(1 - \zeta_T^a)^2 \right)
\]

and that the sets \( B_T \) are

Using Corollary 4 we obtain \( \eta_{T}^{\sigma_{p_{1}}\cdots\sigma_{p_{r}}} = \eta_{T}^{(-1)^{t}} \). Combining these two formulas we obtain another expression for \( \varepsilon_{T} \), namely

\[
\varepsilon_{T} = \pm \prod_{1 \leq a \leq n_{T}} \left( \frac{a_{T}^{\sigma_{p} - a}}{\zeta_{T}^{(1 - \zeta_{p}^{a})^{t}}} \right)
\]

From this expression it can be easily seen (as \(-1\) is a quadratic residue modulo every \( p \in T \)) that \( \varepsilon_{T} \) is generated by \( B_{T} \) modulo roots of unity.

Now, let \( T = \{p\} \). We have

\[
\varepsilon_{\{p\}} = \prod_{i=0}^{(p-3)/2} (\zeta_{p}^{(p-1)/2}(1 - \zeta_{p}^{i}(-1)^{i} = \xi \cdot \prod_{i=0}^{(p-3)/2} (1 - \zeta_{p}(\sigma_{p}^{i} - 1)(-1)^{i})
\]

for a suitable root of unity \( \xi \). For a given \( i \) \((0 \leq i \leq (p-3)/2) \) let \( 1 \leq j < p \) satisfies \((1 - \zeta_{p})^{\sigma_{p}^{i} = 1 - \zeta_{j}}. \) For \( 2 \leq j \leq (p-1)/2 \) the unit \((1 - \zeta_{p})^{\sigma_{p}^{i} - 1} \) clearly belongs to \( B_{\{p\}} \). If \( j = 1 \), then \((1 - \zeta_{p})^{\sigma_{p}^{i} - 1} = 1 \), and if \( j = p-1 \), then \((1 - \zeta_{p})^{\sigma_{p}^{i} - 1} = \frac{1 - \zeta_{p}^{-1}}{1 - \zeta_{p}} = -\zeta_{p}^{-1} \), i.e. a root of unity. Finally, for \((p + 1)/2 \leq j \leq p - 2 \) we obtain

\[
(1 - \zeta_{p})^{\sigma_{p}^{i} - 1} = \frac{1 - \zeta_{j}}{1 - \zeta_{p}} = -\zeta_{p}^{-j} \frac{1 - \zeta_{p}^{-j}}{1 - \zeta_{p}}
\]

Since \( 2 \leq p - j \leq (p - 1)/2 \), the last fraction belongs to \( B_{\{p\}} \) and we have proved that \( \varepsilon_{\{p\}} \) is again generated by the elements of \( B_{\{p\}} \) modulo roots of unity.

**Lemma 7.** \([C_{W}(K) : D] \) is finite.

**Proof.** From Proposition 5 and the definition of \( D \) we know that rank \( C_{S}(K) = \) rank \( D \). Moreover, as \( C_{S}(K) \subseteq C_{W}(K) \subseteq E(K) \), and rank \( C_{S}(K) = \) rank \( E(K) \) by Proposition 2 we obtain rank \( D = \) rank \( C_{W}(K) \).

\( \square \)

**Proposition 8.** Let \( K = \mathbb{Q}(\sqrt{p}; p \in J) \), where \( J \) is a set of positive primes \( p \equiv 1 \) (mod 4) such that for any distinct \( p, q \in J \) we have \((p/q) = 1 \). Then

\[
C_{W}(K) = \langle -1, \varepsilon_{T}; \emptyset \neq T \subseteq J \rangle.
\]

**Proof.** Denote as above the set \((-1, \varepsilon_{T}; \emptyset \neq T \subseteq J \) by \( D \). From the previous lemma we know that there is a positive integer \( f \) such that for any \( w \in C_{W}(K) \) we have \( w^{f} \in D \), i.e.

\[
w^{f} = \pm \prod_{\emptyset \neq T \subseteq J} \varepsilon_{T}^{f_{T}}
\]

for suitable \( f_{T} \in \mathbb{Z} \). From the expression of \( w \) and \( \varepsilon_{T} \) in basis of \( C(\mathbb{Q}(\sqrt{4})) \) we obtain (as the sets \( B_{T} \) are pairwise disjoint and each \( \varepsilon_{T} \) is a multiplicative combination of some elements of \( B_{T} \) with exponents \( \pm 1 \)) that \( f | f_{T} \) for any \( T \), hence \( w \in D \).

\( \square \)

**Theorem.** Let \( K = \mathbb{Q}(\sqrt{p}; p \in J) \), where \( J \) is a set of positive primes \( p \equiv 1 \) (mod 4) such that for any distinct \( p, q \in J \) we have \((p/q) = 1 \).

Then the Washington group of circular units of \( K \) is of finite index in the full group of units and

\[
[E(K) : C_{W}(K)] = h_{K},
\]

where \( h_{K} \) is the class number of \( K \).

**Proof.** From Proposition 2 we know that the Sinnott group \( C_{S}(K) \) is of finite index in \( E(K) \) and that in our case

\[
[E(K) : C_{S}(K)] = 2^{2^{h_{J} - 1}} \cdot h_{K}.
\]
As \( C_W(K) = \langle -1, \varepsilon_T; \emptyset \neq T \subseteq J \rangle \), \( C_S(K) = \langle -1, \varepsilon_T^2; \emptyset \neq T \subseteq J \rangle \), and rank \( C_W(K) = \text{rank} C_S(K) = 2^{|J|} - 1 \), we have
\[
[C_W(K) : C_S(K)] = 2^{|J| - 1},
\]
and therefore \([E(K) : C_W(K)] = h_K\). □
